Abstract

We describe a new species of *Selvasaura* from the montane forests of the eastern slopes of the Andes in northern Peru, based on external and hemipenial morphological characters and previous phylogenetic analyses. The new species can be differentiated from the other two *Selvasaura* species in having keeled dorsal scales usually flanked by longitudinal striations, in adults and juveniles; adult males with a yellow vertebral stripe bordered by broad dark brown stripes on each side and a unilobed hemipenis surrounded by the branches of the sulcus spermaticus. The description of the new species contributes information about new states of diagnostic characters of *Selvasaura* and natural history.

Key Words

Arboreality, Bromeliad, Gymnophthalmidae, Hemipenial morphology, Peruvian Yungas ecoregion, Taxonomy

Introduction

The subfamily Cercosaurinae is the most diverse taxon of Gymnophthalmidae, currently containing 22 genera. In the last five years, several Cercosaurinae genera have been described or resurrected (e.g., Torres-Carvajal et al. 2016; Sánchez-Pacheco et al. 2018; Lehr et al. 2019, 2020; Vásquez-Restrepo et al. 2020; Rojas-Runjaic et al. 2021). The fast pace of generation of knowledge about the diversity of Cercosaurinae is, in part, due to the inclusion of samples from little-surveyed localities in recently published phylogenies (Goicoechea et al. 2013, 2016; Torres-Carvajal et al. 2016; Sánchez-Pacheco et al. 2017; Moravec et al. 2018; Fang et al. 2020; Mamani et al. 2020; Vásquez-Restrepo et al. 2020). These studies have revealed that the highly diverse montane forests of the eastern slopes of the Andes of Peru

(Young and León 2000) harbor new and endemic lineages of Cercosaurinae lizards (Goicoechea et al. 2013; Chávez and Catenazzi 2014; Echevarría et al. 2015; Mamani et al. 2015, 2020; Venegas et al. 2016; Chávez et al. 2017; Moravec et al. 2018; Lehr et al. 2019, 2020; Torres-Carvajal et al. 2020).

A clade of microteiid lizards, including samples from Ecuador and Peru, was identified as not nested in any recognized Cercosaurinae genus by Torres-Carvajal et al. (2016). Subsequently, Moravec et al. (2018) described this clade as the genus *Selvasaura*, including a single species, *S. brava* Moravec, Šmid, Štundl & Lehr, 2018, an arboreal lizard from the eastern montane forests of the Andes of central Peru. Another species of *Selvasaura* was described from the Amazonian slopes of the Andes of Ecuador based on morphological and molecular data (Torres-Carvajal et al. in press). In their phylogenetic tree,

Torres-Carvajal et al. (in press) recovered an unnamed clade of *Selvasaura* from northern Peru sister to *S. brava* in agreement with previous studies (Torres-Carvajal et al. 2016; Moravec et al. 2018; Fang et al. 2020). Based on external and hemipenial morphological characters here we describe this clade as a new species of *Selvasaura* from the montane forests of northern Peru.

Materials and methods

Field surveys

Specimens were collected during four field surveys conducted between 2014 and 2020. Field surveys to Laurel and Fundo Alto Nieva, in San Martín department, were conducted during the wet season in November 2014 and January 2020, respectively. Surveys in Amazonas department, at Copal and Quebrada Gajmal, were conducted in June 2017 and October 2018 during the dry season and transition from dry to wet season, respectively. Anurans and reptiles were actively searched using the visual encounters (VES) method (Crump and Scott 1994) and collected by hand. All collected specimens were preserved in 10% formalin and stored in 70% ethanol (Barry 2012). Tissue samples were taken from the liver, tail or tongue and stored in 96% ethanol. Type specimens were deposited in the herpetological collection at Centro de Ornitología y Biodiversidad (CORBIDI) in Lima, Peru.

Morphology

The following measurements were taken, to the nearest 0.1 mm, with a digital caliper: head length (HL), head width (HW), shank length (ShL), axilla-groin distance (AGD), and snout-vent length (SVL). Tail length (TL) was measured with a ruler and recorded to the nearest millimeter. Except for males with everted hemipenes, a short incision in the base of the tail was made to check for the presence of hemipenes. The volume of oviductal eggs was calculated in two gravid females (CORBIDI 15118 and 15120) with the formula for a prolate spheroid $V = 4/3\pi \cdot (\text{length}/2) \cdot (\text{width}/2)^2$. We described the coloration in life from photographs.

Definitions of morphological characters follow Kizirian (1996). The format of the description follows Moravec et al. (2018) and Torres-Carvajal et al. (2014). For comparisons, morphological information was taken from Moravec et al. (2018), Torres-Carvajal et al. (in press) and examination of type specimens (Appendix 1). The *Selvasaura* species described by Torres-Carvajal et al. (in press) will be referred to as *Selvasaura* sp. Ecuador.

Hemipenial morphology

The left hemipenis of the holotype CORBIDI 15119 was prepared following the procedures described by Manzani and Abe (1988), modified by Pesantes (1994) and Zaher

(1999). The organ was everted after immersion in potassium hydroxide solution for approximately 15 minutes. The retractor muscle was manually separated, and the everted organ filled with stained petroleum jelly. The organ was then immersed in alcoholic solution of Alizarin Red for 24 hours in order to stain calcified structures (e.g., spines or spicules), in an adaptation proposed by Nunes et al. (2012) of the procedures described by Uzzell (1973) and Harvey and Embert (2008). The terminology of hemipenial structures follows previous literature (Nunes et al. 2012).

Genetic distances

We used MEGA (Kumar et al. 2016) to calculate uncorrected genetic distances for 12S (337 pb fragment), 16S (452 pb fragment), c-mos (381 pb fragment), and ND4 (621 pb fragment). Uncorrected genetic distances were calculated between *S. brava*, *S. sp.* Ecuador, the new species, and *S. sp.* QCAZ 12891 (an undescribed species from Ecuador). For ND4 uncorrected genetic distances did not include *Selvasaura brava*, once there is no available data for ND4 from this species.

Species concept

We followed the evolutionary species concept (Simpson 1951; Wiley 1978; de Queiroz 1998, 2007). We used morphological features to diagnose as a species a monophyletic group previously inferred through phylogenetic analysis of DNA sequences.

Results

The allocation of the new species in the genus *Selvasaura* is based on previously published phylogenetic evidence (Torres-Carvajal et al. 2016, in press; Moravec et al. 2018). Phylogenetic divergences presented in earlier studies (Torres-Carvajal et al. 2016, in press; Moravec et al. 2018) and the combination of diagnostic morphological characters (external and hemipenial) allowed the identification of the specimens in our hands as an unnamed *Selvasaura* species, described below.

Uncorrected genetic distances among *Selvasaura* were 4.8–6.3% for 12S; 4.7–5.2% for 16S; 0.3–0.8% for c-mos; and 13–14% for ND4 (Appendix 2).

Holotype. PERU • ♂, adult; San Martín Department, Mariscal Cáceres Province, Huicungo District, Laurel; 06°41'2"S, 77°41'44.3"W; 2,762 m; 02 Nov. 2014; L.Y. Echevarría, A.C. Barboza and J. Briones leg.; CORBIDI 15119 (Figs 1, 2).

Paratypes. PERU • 2 ♀ adults, 1 ♀ subadult, 2 juveniles, collected with the holotype; CORBIDI 15118 (Fig. 3A, B), 15120, 15117, 15115–16 • 2 ♂ adults; Amazonas Department, Bongará Province, Yambrasbamba District, Copal; 05°46'36.317"S, 77°50'47.197"W; 2,582 m; 22 Jun. 2017; P.J. Venegas and J.C. Chávez-Arribasplata leg.; CORBIDI 18900 (Fig. 3C, D), 18901 • 1 juvenile; Amazonas Department, Chachapoyas Province, Chachapoyas District, Gajmal; 06°16'30.885"S, 77°41'41.896"W; 2,139 m; 13 Oct. 2018; P.J. Venegas and L.A. García-Ayachi leg.; CORBIDI 19955 (Fig. 3E, F) • 1 ♂ adult; San Martín Department, Rioja Province,

Pardo Miguel District, Fundo Alto Nieva 05°40'13.919"S, 77°45'45.475"W; 1,938 m; 23 Jan. 2020; L.A. García-Ayachi and J. Ormeño leg.; CORBIDI 22197.

Characterization. A small gymnophthalmid (SVL 51.1–52.2 mm [$n = 2$] in females and 41.9–46.1 mm [$n = 4$] in males) characterized by: 1) body slender; 2) head pointed, 1.4 to 1.6 times longer than wide; 3) ear opening distinct, moderately recessed; 4) nasals separated by undivided frontonasal; 5) prefrontals, frontal, frontoparietals, parietals, postparietals and interparietal present; 6) parietals longer than wide; 7) three supraoculars; 8) superciliar series complete, consisting of four scales; 9) nasal completely or partially divided (behind the nostril); 10) loreal in contact with second supralabial; 11) supralabials usually seven; 12) two pairs of genials; 13) collar present, composed by 9–10 enlarged scales; 14) 33–38 transverse rows of dorsal scales; 15) 20–25 transverse rows of ventral

Figure 2. Dorsolateral (A) and ventral (B) views of *Selvasaura evasa* sp. nov. holotype, CORBIDI 15119, in life. Photographs by L.Y. Echevarría.

scales; 16) 10–12 longitudinal rows of ventral scales; 17) 44–50 scales around midbody; 18) lateral scales at mid-body reduced or absent, present in a maximum of three rows; 19) limbs pentadactyl, all digits clawed; 20) subdigital lamellae under Finger IV 14–19, under Toe IV 17–24; 21) femoral pores 7–10 in females and 9–12 in males; 22) cloacal plate with four large scales; 23) tail 1.3–1.9 times longer than body; 24) caudals keeled dorsally and smooth ventrally; 25) lower palpebral disc undivided, pigmented or transparent; 26) dorsum brown with a yellow vertebral stripe, bordered by broad dark brown

stripes in adult males; 27) cream labial stripe extending up to insertion of forelimb in males, females and juveniles; 28) sides of body brown and cream on ventrolateral region in males, females and juveniles; 29) well defined ocelli usually absent; adults and juveniles with a row of faint ocelli (black outline and cream center) followed by cream spots, usually up to midbody.

Diagnosis. *Selvasaura evasa* sp. nov. can be distinguished from *S. brava* (character states in parentheses) by having 0–3 lateral rows of reduced scales at midbody (6–7); 9–12 femoral pores in males (7–9); keeled dorsal

Figure 3. Paratypes of *Selvasaura evasa* sp. nov.: dorsolateral (A) and ventral (B) views of adult female CORBIDI 15118; dorsolateral (C) and ventral (D) views of adult male CORBIDI 18900; dorsolateral (E) and ventral (F) views of juvenile CORBIDI 19955. Photographs A, B by LYE and C–F by PJV.

scales, usually flanked by longitudinal striae in adults and juveniles (slightly rugose in adults and slightly keeled in juveniles); ventral surface of tail orange in adult males (yellowish white); and a unilobed hemipenis (bilobed). *Selvasaura evasa* sp. nov. can be distinguished from *S. sp.* Ecuador (character states in parentheses) by having a larger size, SVL 41.9–46.1 mm, $n = 3$, in adult males (maximum SVL 39.7 mm); keeled dorsal scales, usually flanked by longitudinal striae (striated); 33–38 transverse rows of dorsal scales (25–32); 10–12 longitudinal rows of ventral scales at midbody (8–10); 9–10 scales on collar (7–9); a yellow vertebral stripe with broad dark brown stripes on each side in adult males (cream or gray with scattered black marks along sides).

Description of holotype. Adult male (CORBIDI 15119); SVL 44.8 mm; TL 86.0 mm; dorsal and lateral head scales juxtaposed, smooth; rostral rectangular, 1.9 times as wide as high; frontonasal pentagonal, as long as wide, laterally in contact with nasals, same size than frontal; prefrontals pentagonal, longer than wide, with medial suture, laterally in contact with nasal, loreal and first superciliary; frontal hexagonal, longer than wide, slightly wider anteriorly, in contact with frontoparietals, prefrontals and supraoculars I and II; frontoparietals pentagonal, longer than wide, with medial suture, each in contact laterally with supraoculars II and III; interparietal hexagonal, lateral borders parallel to each other; parietals polygonal, positioned anterolaterally to interparietal, each in contact

laterally with supraocular III and dorsalmost postocular; postparietals three, medial one smaller than laterals; 8/7 (right/left) supralabials, fourth below center of eye; six infralabials, fourth below center of eye; temporals enlarged, juxtaposed, smooth; two large, smooth supratemporal scales; nasal divided in two, subtriangular, in contact with rostral anteriorly, first and second supralabials ventrally, frontonasal and prefrontal dorsally and loreal posteriorly; nostril piercing nasal in the center, directed lateroposteriorly; loreal pentagonal; frenocular subtriangular, in contact with loreal, first subocular and third supralabial; three supraoculars, first one the largest; four superciliaries, first one the largest and dorsally extended in contact with prefrontal and loreal; lower eyelid scale single and pigmented; four suboculars, fourth one the largest; three postoculars, similar in size; ear opening round without denticulate margins; tympanum recessed into a shallow auditory meatus; mental wider than long; postmental pentagonal, slightly wider than long, followed posteriorly by two pairs of genials; gulars imbricate, smooth, in ten rows; gular fold complete; posterior row of gulars (collar) composed by enlarged scales, twice as large as anterior gulars.

Scales on nape wider than dorsals; scales on sides of neck small and granular; dorsal scales elongated, imbricate, arranged in transverse rows; scales on dorsal surface of neck striated; 33 dorsal scales between occipital scales and posterior margin of hind limbs; 21 dorsal scales rows in a transverse line at midbody; ventrolateral scales smooth; dorsals separated from ventrals by one (right) or two (left) rows of small scales at the level of the 10th transverse row of ventrals; lateral body fold present; ventrals smooth, longer than wide, arranged in 22 transverse rows between collar fold and preanals; 10 ventral scales in a transverse row at midbody; subcaudals smooth; limbs overlap when adpressed against midbody; axillary region composed of granular scales; scales on dorsal surface of forelimb striated, imbricate; scales on ventral surface of forelimb granular; three thick, smooth thenar scales; supradigitals (right/left): 3/3 on finger I, 7/7 on II, 9/9 on III, 11/11 on IV, 7/7 on V; supradigitals 4/4 on toe I, 6/6 on II, 10/10 on III, 12/11 on IV, 9/9 on V; subdigital lamellae on fingers divided proximally and single distally, 7/7 on finger I, 12/13 on II, 16/16 on III, 16/19 on IV, 12/13 on V; subdigital lamellae on toes divided proximally and single distally, 7/7 on toe I, 12/10 on II, 17/16 on III, 22/22 on IV, 15/15 on V; groin region with small, imbricate scales; scales on dorsal surface of hind limbs striated, imbricate; scales on ventral surface of hind limbs smooth, imbricate; scales on posterior surface of hind limbs granular; 10 femoral pores on each thigh; preanal pores absent; two anterior and four posterior cloacal plate scales.

Measurements and proportions of the holotype in mm: HL 10.6, HW 7.1, ShL 5.5, AGD 25.4; TL/SVL 1.9; HL/SVL 0.2; HW/SVL 0.2; ShL/SVL 0.1; AGD/SVL 0.6.

Color of holotype in life. Dorsum brown with a broad yellow vertebral stripe bordered by a broad dark brown stripe on each side, and extending from interparietal to base of tail, where it becomes a light brown stripe.

The vertebral stripe is continuous with a light brown stripe on the dorsal surface of the tail. Dorsal surface of head brown with pale yellow suffusion on frontoparietals and frontal. Lateral surface of head brown. Iris orange. Supralabials and infralabials cream with brown mottling. Cream labial stripe extending posteriorly up to insertion of forelimb. Flanks of body brown, ventrolateral region cream. A longitudinal row of small pale-yellow spots on dorsolateral region. Flanks with two faint ocelli followed by small cream spots, from forelimb insertion to base of tail. Dorsal surface of tail light brown with orange splotches on the sides. Dorsal surface of forelimbs and hind limbs brown; only fingers I and II and toes I and II yellow. Ventral surface of head cream with brown flecks. Ventral surfaces of neck, chest and belly cream with blurred brown splotches on each scale. Ventral surface of tail orange. Ventral surface of forelimbs and hind limbs yellow with brown flecks.

Color of holotype in preservative. Similar to coloration in life. Suffusion on frontoparietals and frontal cream; ventral surface of forelimbs and hind limbs cream with brown spots; ventral surface of tail pale pink on anterior third and cream on the remainder.

Variation. Variations in scale counts and SVL of *Selvasaura evasa* sp. nov. and comparisons with congeners are presented in Table 1.

Two juvenile (CORBIDI 15116 and 19955) and two adult male (CORBIDI 18900–01) specimens have keeled dorsal scales, without the usual striae flanking the central keel. Male specimens CORBIDI 18900–01 and CORBIDI 22197 lack rows of lateral scales. Specimen CORBIDI 15118 has five superciliaries on left side. Specimen CORBIDI 15118 has six supralabials on left side, and CORBIDI 19955 has eight. The number of infralabial scales is quite variable, 5/5 (CORBIDI 15116), 6/5 (CORBIDI 15118), 6/7 (CORBIDI 15115), 7/7 (CORBIDI 15117, 18900, 19955), and 7/8 (18901). Femoral pores are absent only in one juvenile specimen (CORBIDI 19955).

All adult males have a similar coloration, only CORBIDI 22197 has a light brown vertebral stripe. Adult females are similar in color to adult males. However, the

Table 1. Variation in scutellation and sexual dimorphism in SVL (mm) of *Selvasaura evasa* sp. nov. and its congeners, *S. brava* and *S. sp.* Ecuador.

Character	<i>Selvasaura evasa</i> sp. nov. (n = 7)	<i>Selvasaura brava</i> (n = 6)	<i>Selvasaura</i> sp. Ecuador (n = 3)
Scales in collar	9–10	9–11	7–9
Transverse rows of dorsals	33–38	33–36	25–32
Laterals at midbody	0–2	6–7	5
Transverse rows of ventrals	20–25	22–25	20–23
Longitudinal rows of ventrals	10–12	10	8–10
Scales on cloacal plate	4–5	4	4
Lamellae under Finger IV	14–19	14–16	12–16
Lamellae under Toe IV	17–24	18–22	18–20
Femoral pores in females (one leg)	7–10	0	unknown
Femoral pores in males (one leg)	9–12	7–9	9–12
Maximum SVL in females (mm)	52.2	42.1	unknown
Maximum SVL in males (mm)	46.1	45.9	39.7

Figure 4. Left hemipenis of *Selvasaura evasa* sp. nov. (CORBIDI 15119 – holotype) in sulcate (left), lateral (middle), and asulcate (right) views. Photographs by PMSN.

vertebral stripe in females, when present, has a different color pattern. Subadult female specimen CORBIDI 15117 has a light brown vertebral stripe with scattered dark brown spots along margins. Female specimen CORBIDI 15118 (Fig. 3A, B) lacks a vertebral stripe and has two faint black stripes along the dorsolateral margins of the tail. Females lack orange spots on the lateral surface of tail. The ventral surface of tail in females is cream with brown flecks (CORBIDI 15118) or cream with orange margins (CORBIDI 15117).

Juvenile specimens CORBIDI 15115–16 are similar in color to adult males. However, the broad dark brown stripes on each side of the vertebral stripe are discontinuous. Ventrally, the brown flecks on head and the brown splotches on neck, chest and belly are more conspicuous. The tail is orange (CORBIDI 15115) or cream (CORBIDI 15116) ventrally. Specimen CORBIDI 19955 (Fig. 3E, F) has a dark brown dorsum with abundant black flecks and a cream vertebral stripe. It is the only specimen with well-defined ocelli on the anterior portion of flanks, three and seven on right and left sides, respectively, followed by faint ocelli.

One to four faint ocelli (black outline and cream center) are present on the flanks of adult and juvenile specimens. These ocelli are usually followed by cream spots, except in CORBIDI 15118 (Fig. 3A, B) and CORBIDI 18901. Adult female CORBIDI 15117 and adult male CORBIDI 22197 lack ocelli and have a row of three cream spots. The iris is orange, except in one adult female (CORBIDI 15118) and a juvenile (CORBIDI 15115) which have a yellow iris.

Hemipenial morphology. The left hemipenis of the holotype is completely everted and fully expanded, 5 mm long (~four subcaudals); organ unilobed, capitate, with lobe detached from body and bordered by the branches

of the sulcus spermaticus; sulcus spermaticus broad and shallow throughout the hemipenial body, originating at the base of the hemipenis, central in position, and extending in a straight line until it divides into two branches at the half-length of the organ; sulcal branches separated by fleshy fold. Hemipenial body roughly Y-shaped with 15 pairs of transversal flounces, separated by a longitudinal nude area on asulcate face, except for the first five proximal-most flounces; all flounces ornamented with calcified spicules (Fig. 4).

Distribution and natural history. *Selvasaura evasa* sp. nov. is known from four localities along the eastern slopes of the Andean Cordillera Central, in Amazonas and San Martín departments, northern Peru, at elevations from 1,938 to 2,762 m (Fig. 5). All localities lie in the Peruvian Yungas ecoregion (Olson et al. 2001). Individuals collected at Laurel, in San Martín department, were found in the morning of a cloudy day, inside bromeliads, at ground level and up to 2 m above the ground, in a patch of poorly drained soil covered by *Sphagnus* mosses, with scattered shrubs and bromeliads. All specimens were lying inside the water stored in the bromeliads; only CORBIDI 15120 was found dead on the ground, beginning to decompose, missing the right hind limb and a portion of the tail, and with the head partially eaten. Specimens from Copal, in Amazonas department, were found on the border of a small lagoon, under a rock (CORBIDI 18900) and among trash (CORBIDI 18901) in a patch of bunchgrass. Specimen CORBIDI 22197 from Fundo Alto Nieva, was found crossing a road in an area of dense montane forest. Specimen CORBIDI 19955, from Quebrada Gajmal, was collected when it fell from the stick roof of a house surrounded by cattle pasture and patches of secondary montane forest.

Figure 5. Distribution map of *Selvasaura*. Symbols with a dot in the middle correspond to type localities.

The two adult females collected at Laurel were gravid, each with two eggs. Specimen CORBIDI 15118 had eggs 12.7–13.7 mm long, 6.1 mm wide and 247.3–266.8 mm³ of volume. Specimen CORBIDI 15120 had eggs 12.7–13.4 mm long, 5.6–5.9 mm wide and 208.4–244.1 mm³ of volume.

Etymology. The specific epithet *evasa* is derived from the Latin adjective *ēvāsa* meaning scaped and refers to the evasive nature of this species. The first specimens of *Selvasaura evasa* sp. nov. were collected in 2014 despite continuous surveys, since 2003 in 20 localities along the montane forests of Amazonas and San Martín departments, it is only known from four localities.

Discussion

The results of Moravec et al. (2018) and the Maximum Likelihood tree of Torres-Carvajal et al. (in press) recovered *Selvasaura evasa* as sister to the clade composed by *S. brava* and an undescribed species from Ecuador (QCAZ 12891). The results of Fang et al. 2020 (see the supplemental files) recovered *S. evasa* as sister to a clade composed by *S. sp. Ecuador* (named as *Selvasaura* sp. – QCAZ 12798) and an undescribed species from Ecuador (QCAZ 12891). The Bayesian Inference tree of Torres-Carvajal et al. (in press) recovered *S. evasa* sp. nov. as sister

to an undescribed species from Ecuador (QCAZ 12891), and this clade as sister to *Selvasaura* sp. Ecuador. Genetic distances for 12S, 16S, and c-mos among *Selvasaura* species are similar or higher to the mean genetic distances between *Selvasaura* and *Dendrosauridion* or *Potamites* (Moravec et al. 2018, tables 3, 4), the two Cercosaurinae genera known to be more closely related to the genus (Torres-Carvajal et al. 2016, in press; Moravec et al. 2018; Fang et al. 2020; Vásquez-Restrepo et al. 2020). Therefore, although the results of all previous phylogenetic analyses, the genetic distances and the external and hemipenial morphological characters consistently support *S. evasa* sp. nov. as a distinct and monophyletic lineage in the genus *Selvasaura*, the relationships between *S. evasa* sp. nov. and its congeners are still uncertain, which prevents us from postulating consistent biogeographic scenarios involving the new species.

The description of a new species of *Selvasaura*, contributes new states of diagnostic characters of the genus: dorsal scale relief, pigmentation of lower palpebral disc, and presence of femoral pores in females. Furthermore, although the unlobed hemipenes are described and illustrated to *Selvasaura* sp. Ecuador (Torres-Carvajal et al. in press) and to *S. evasa* sp. nov. (this study), the unlobed condition was not reported to *S. brava*, with the organ being described as bilobed by Moravec et al. (2018). However, it is important to consider that Moravec et al. (2018) described the hemipenial morphology *in situ* and did not applied specific hemipenial preparation procedures or presented detailed illustrations of the hemipenial morphology to *S. brava*, presenting pictures of an unexpanded and partially everted organ (Moravec et al. 2018 – fig. 7C; MorphoBank pictures: [M485676–M485677](#)). Considering the unlobed hemipenis as an uncommon condition in the family Gymnophthalmidae, present only in the subfamily Gymnophthalminae (Nunes 2011; Torres-Carvajal et al. in press) and as an exclusive characteristic of *Selvasaura* species within the subfamily Cercosaurinae, the reanalysis of the hemipenis of *S. brava* is desirable. The unlobed condition of the hemipenis as a putative synapomorphy to the genus should be considered until then.

Additionally, the description of *Selvasaura evasa* sp. nov. contributes with natural history information for this recently discovered and poorly known Andean genus. It is reinforced that the arboreal habitat is still little explored in gymnophthalmids (Chávez et al. 2017; Moravec et al. 2018; Lehr et al. 2019); in fact, *S. evasa* sp. nov. is one of the few gymnophthalmids known to use the inside of bromeliads as refuge (Ofstedal 1974; Fuentes and Rivas 2000; Mijares-Urrutia et al. 2000; Kok 2008; Chávez et al. 2017; Lehr et al. 2019). So far, all known *Selvasaura* specimens come from localities east of the Andes (Torres-Carvajal et al. 2016, in press; Moravec et al. 2018) along more than 1200 km in straight line from the northern to the southern-most locality. The diversity of the genus and the distribution and natural history of the described species remain to be further studied.

Acknowledgements

The new species of *Selvasaura* was discovered during fieldwork supported by: Critical Ecosystem Partnership Fund (CEPF) and Fondo de Promoción de las Áreas Naturales Protegidas del Perú (PROFONANPE) with the projects: Updating the status of an endemic harlequin frog from Peru (project number CEPF-108792) and Community forest conservation in the northeastern biodiversity corridor in Peru (project number CEPF-66127); APECO under the research grant “Carlos Ponce del Prado Award (XI edition)”; Global Genome Initiative (GGBN–GGI); and NGO’s Ucumari and Yunkawasi. Fieldwork would not have been possible without the logistic support of the following people: Marco Salas from Ucumari, Fanny M. Cornejo from Yunkawasi, Odile Sanchez from PROFONANPE, Mariela Leo and Glen Seitz from APECO. We are especially grateful with our field companions: LYE is indebted to Andy Barboza, Joaquín Briones, and Marco Salas; AGA is indebted to Jesús Ormeño; PJV is indebted to Juan C. Chávez. PJV is grateful to Rainforest Partnership for funding his herpetological research during 2021. PMSN is supported by Conselho Nacional de Desenvolvimento Científico e Tecnológico – CNPq (fellowship number 313622/2018-3). The authors are grateful to William W. Lamar for revising the English language of the manuscript. The authors are grateful to the Centrum für Naturkunde (CeNak) – Center of Natural History – University of Hamburg for supporting the publication of Evolutionary Systematics.
